#### Data Science Methods - Assignment 1

M. Alberti, 2020162

N.R. Ceschin

February 21, 2020

First we upload all relevant libraries:

```
library(readx1)
library(ggplot2)
library(ggfortify)
library(dplyr)
library(tidyr)
library(RCurl)
library(ggrepel)
```

#### Upload dataset:

```
setwd("C:/Users/Mr Nobody/Desktop/Uni/EME/Data science Methods/Assignments")
#setwd("~/Tilburg/Courses/Data Science Methods/Assignment1/DATA-SCIENCE-ASSIGNMENTS")
data<-read_excel("env_air_emis.xls")
x <- getURL("https://raw.githubusercontent.com/AlbertiMarco/DATA-SCIENCE-ASSIGNMENTS/master/EU%20labels
EU_labels<- read.csv(text = x, header = FALSE ,sep=";") #import country tags to make plots more readabl
rownames(EU_labels)<-EU_labels[[1]]</pre>
```

After a quick glimpse of the data we realized that information for the five pollutant are presented in separated consecutive tables, the separation contains some information in the first column and NA cells in the rest. To be sure not to drop NAs in the middle of the dataset, we first proceed to drop all raws containing at least 5 NA values and we assign to df:

```
dim(data)
df<-data[rowSums(is.na(data))<length(data)-5,]
#df<-data[complete.cases(data), ]</pre>
```

Given the data structure and the exercises a-c requests, we decided that the optimal approach would be looping over the chunks of data containing information for each pollutant, producing without repeting the code the outputs all in one step. First we create some variables that will be used in the loop:

```
#build 'index' for your loop
interval<-c(1,30,59,88,117)  #number of the first row of each individidual dataset
pollutants<-c("ammonia", "nmvoc", "smallpart", "largepart", "sulphur")
index<-data.frame(interval,pollutants)

PC1<-data.frame(matrix(ncol=5,nrow=28))  #empty data frames that will be filled with the scores
PC2<-data.frame(matrix(ncol=5,nrow=28))  # of the PC 1 and 2 for each pollutant and country

mytheme <- theme(plot.title= element_text(face="bold",colour = "antiquewhite4",size = (16),hjust = 0.5)

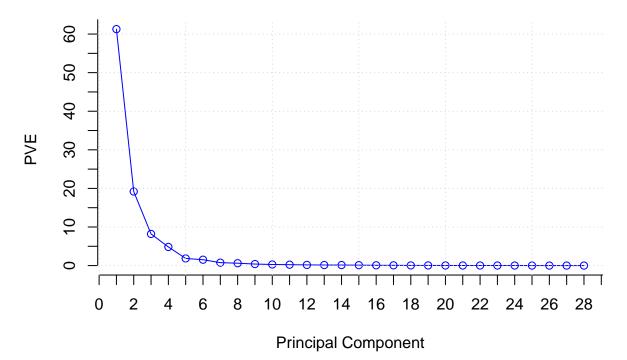

for (i in 1:5){
    #data chunk preparation
    begin<-index[i,1]</pre>
```

```
end<-index[i,1]+28 #each chunk has 27 countries plus the first raw with years
dfx<-df[begin:end,] #slice portion of the dataframe, 'according to begin' and 'end'
dfx <- as.data.frame(dfx) #rename first column with the name of the pollutant
colnames(dfx)<-dfx[1,]</pre>
                              #set first column as observations' names and first row as
                                                                                             variab
rownames(dfx)<-dfx[,1]</pre>
dfx<-dfx[c(2:29),c(2:29)]
                              #drop first column and obtain the final datset
if (sum(mapply(grepl,rownames(EU_labels),rownames(dfx)))==length(dfx)) {
rownames(dfx)<- EU labels[[2]]</pre>
 } #Substitute name with short labels of the appropriate country
dfx<-as.data.frame(t(dfx))</pre>
                           #convert factor columns into numeric to apply prcomp
indx <- sapply(dfx, is.factor)</pre>
dfx[indx] <- lapply(dfx[indx], function(x) as.numeric(as.character(x)))</pre>
#Principal Component Analysis
pr.out<-prcomp(dfx, scale=TRUE)</pre>
#print(pr.out$rotation[,1:2])
                                       # print first two PC loadings and plot first two PC
graph<-autoplot(pr.out, variance_percentage=FALSE, loadings=TRUE,</pre>
        loadings.label=TRUE,loadings.label.repel=TRUE,loadings.colour="coral",loadings.label.size=3,
pve= 100* (pr.out$sdev ^2)/ sum(pr.out$sdev ^2) #screeplot
scree<-plot(pve , type ="o", ylab="PVE ", xlab=" Principal Component ",</pre>
    col =" blue",axes = F)
axis(side = 1, at = seq(from=0,to=30))
axis(side = 2, at = seq(from=0, to=100, by=5))
title(paste("Scree plot for PCs of",toString(index[i,2]),"pollutant"))
grid()
#compute vector of BIC for first 27 principal components
BIC<-c(1:27) #initialize a numeric vector to be filled with BIC(k) values. set max k=p-1
for (j in 1:27) {
 f<-t(pr.out\$rotation[,1:j])%*%pr.out$x[,1:j] #compute aF in X=aF+e
 res_mat<-dfx[,1:j]-f
                                       #compute matrix of residuals
 res_mat_sq<-res_mat*res_mat
                                              #square residuals
 if (j==1){
   res<-(sum(res_mat_sq)/(dim(dfx)[1]*dim(dfx)[2]))
 res<-(sum(rowSums(res_mat_sq))/(dim(dfx)[1]*dim(dfx)[2]))
                                                                 #residuals sum of squares
 k<-j
 BIC[j]<-BICk
                                              #fill BIC vector at each iteration
 }
min<-min(BIC)
num_pc<-match(min,BIC)</pre>
                                              #find and print k, the index of the min of BIC
cat("According to the BIC criterion, the optimal number of principal components is ", num_pc)
###potential issue: smallest value for BIC is always the one with ###
###the max number of principal components...strange! I checked the calculations ###
###and they seem fine. I think the issue is that the penalty part of BIC is really###
###trivial compared to the log(SSR) part####
#save first two PC in separate dataset for point d)
```

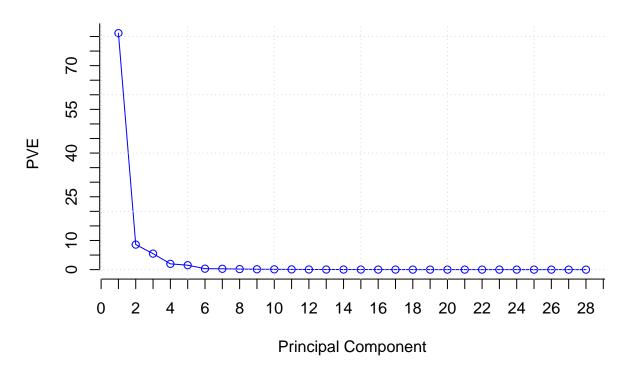

```
PC1[i] <-pr.out$x[,1]
colnames(PC1)[i] <-as.character(index[i,2])
PC2[i] <-pr.out$x[,2]
colnames(PC2)[i] <-as.character(index[i,2])

#save relevant objects with their respective name
assign(paste0("BIC_", index[i,2]), BIC)
assign(paste0("df_", index[i,2]), dfx)
assign(paste0("prcomp_",index[i,2]),pr.out)
assign(paste0("Screeplot_",index[i,2]),scree)
assign(paste0("PC1-PC2_",index[i,2]),graph)
#remove non relevant objects
rm(dfx)
rm(BIC)
rm(pr.out)
}</pre>
```

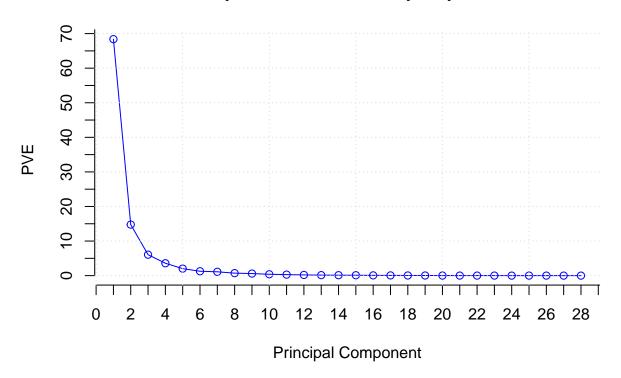

### Scree plot for PCs of ammonia pollutant

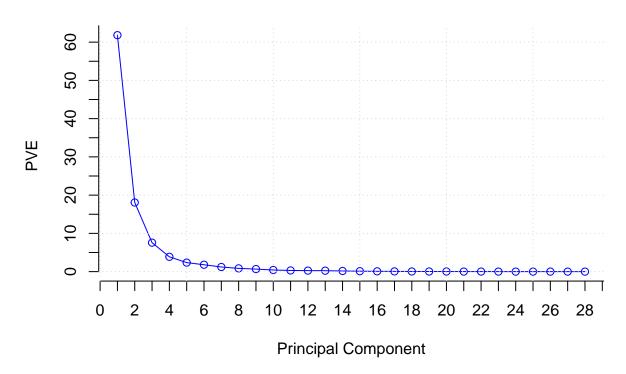

# Scree plot for PCs of nmvoc pollutant

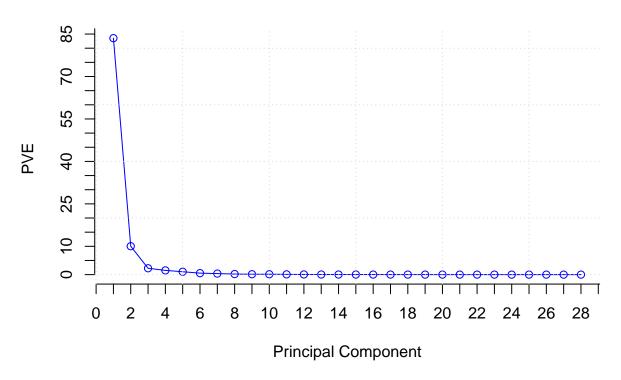

# Scree plot for PCs of smallpart pollutant

# Scree plot for PCs of largepart pollutant

#### Scree plot for PCs of sulphur pollutant

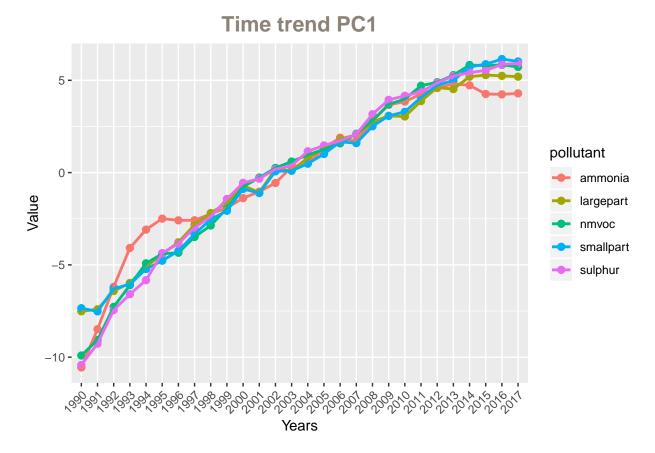

#### d): Plot first 2 principal components Time trends

Code to produce the plots:

Here is the plot of the first principal component over time for the five pollutant in the dataset:

```
print(PC1_plot)
```

Here is the same plot for the second principal component:

print(PC2\_plot)
